

## Hemolytic Uremic Syndrome<sup>☎</sup>

(HUS)

### What is Hemolytic Uremic Syndrome?

Hemolytic uremic syndrome (HUS) is a life-threatening illness that affects the red blood cells and kidneys. It is a rare condition, but is more common in children, especially those younger than five years of age. HUS often occurs after a gastrointestinal infection with *Escherichia coli* O157:H7, a type of shiga-toxin producing *E. coli* (STEC). About 5-10 percent of people diagnosed with STEC develop HUS. The condition has also been linked to other bacterial pathogens known to cause gastrointestinal infections, including *Shigella* and *Salmonella*.

### Who is at risk for HUS?

Anyone can get HUS, but children under five and the elderly are at higher risk.

### What are the symptoms of HUS?

Symptoms of HUS may include fever, fatigue, irritability, blood in urine and decreased urination or no urination. Anemia, low platelet count and decreased kidney function may also occur.

### How soon do symptoms appear?

Post-diarrheal HUS usually occurs one to two weeks following the onset of diarrhea.

### How is HUS spread?

HUS cannot be spread from person-to-person. However, STEC, *Shigella* and other organisms that can cause HUS can be spread through eating or drinking contaminated food or water or contact with a person who is ill.

### When and for how long is a person able to spread the disease?

HUS cannot be spread from person-to-person, but the bacteria that can cause HUS can be spread. The length of time a person can spread the bacteria is variable, and depends on the type of bacteria.

### How is a person diagnosed?

HUS is diagnosed based on clinical signs and symptoms and the results of several laboratory tests, which include kidney function, blood clotting factors and blood counts.

### What is the treatment?

Treatment for HUS is mostly supportive. Blood transfusions may be necessary if the patient is severely anemic. Dialysis may be required if the patient develops kidney failure.

### Does past infection make a person immune?

No. The illness may recur if the person is exposed again.

### Should children or others be excluded from child care, school, work or other activities if they have HUS?

Yes; most likely, anyone with HUS will be severely ill and require hospitalization.

Please refer to STEC and shigellosis fact sheets as these diseases have particular exclusion criteria.

### What can be done to prevent the spread of HUS?

HUS can be prevented by taking the following precautions against the spread of STEC infections, shigellosis, and other gastrointestinal infections:

- Wash hands thoroughly after using the bathroom or changing diapers and before preparing or eating food. Wash hands after contact with animals or their environments (i.e., farms, petting zoos, fairs).
- Cook all ground beef or hamburger thoroughly. It should be cooked to a temperature of at least 160°F. It is best to use a thermometer, as color is not a reliable indicator.
- If you are served an undercooked hamburger in a restaurant, send it back for further cooking.
- Avoid raw milk, unpasteurized dairy products and unpasteurized juices.
- Avoid swallowing water when swimming or playing in lakes, ponds, streams and swimming pools.
- Prevent cross contamination in food preparation areas by thoroughly washing hands, counters, cutting boards and utensils after they touch raw meat.

For additional information, call the North Dakota Department of Health at 800.472.2180.

**This disease is a reportable condition. As mandated by North Dakota law, any incidence of this disease shall be reported to the North Dakota Department of Health.**
